

ATOMiK

State-aware compute evaluation for edge and embedded teams constrained by battery, heat, bandwidth, latency, reliability, or hardware footprint.

The Customer Problem

Many constrained systems spend too much work rediscovering what changed. They move, scan, sync, replay, or rebuild state even when only a compact delta matters. In edge and embedded systems, that waste can become battery drain, thermal pressure, latency, bandwidth pressure, field-service risk, and hardware overbuild.

Data-center power, cooling, water, and sustainability pressures matter, but they are second-order expansion narratives until ATOMiK has workload-specific measurement in that environment.

What Customers Get

ATOMiK is evaluated where avoided state work may create business value:

- **Lower state-movement cost:** fewer bytes moved, transfers avoided, or scans skipped.
- **Faster constrained state paths:** lower update or reconstruction latency where the path fits.
- **Lower bandwidth pressure:** move compact deltas instead of repeated full-state updates when measured.
- **Power or thermal pressure reduction:** evaluation target when instrumentation or a responsible proxy exists.
- **Clear fit/no-fit evidence:** a decision about whether the workload justifies deeper evaluation.

Battery, heat, cooling, water, footprint, and hardware-profile improvements are evaluation targets until measured on a specific workload.

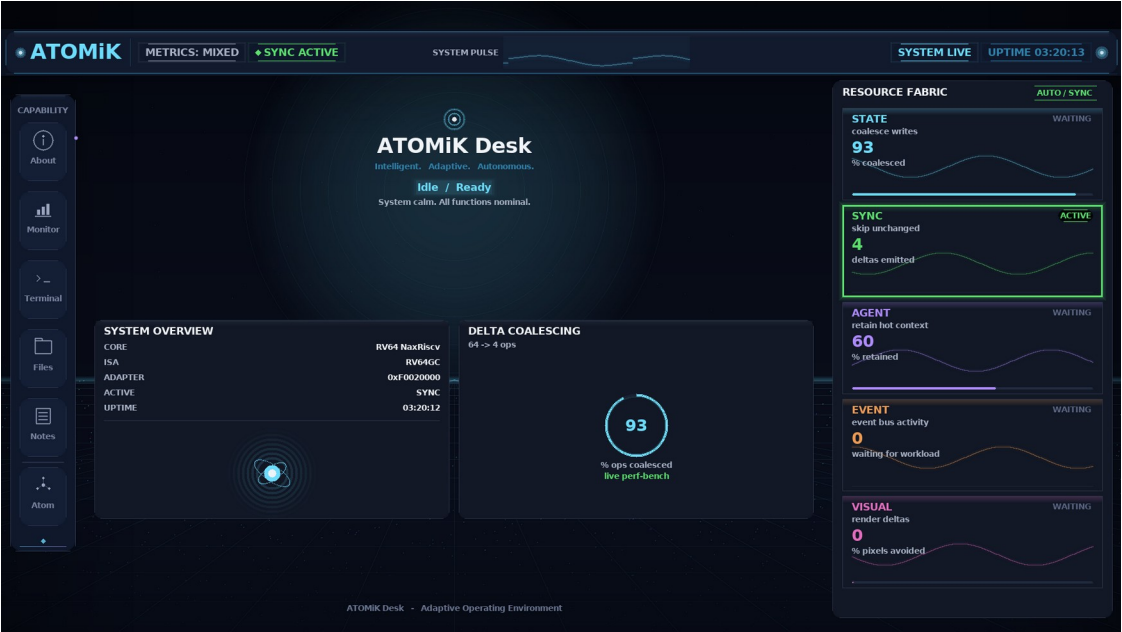

What ATOMiK Is

ATOMiK makes change the unit of compute:

```
state = reference_state XOR accumulated_delta
```

It keeps a known reference state, accumulates compact deltas, reconstructs only when needed, and commits clean state epochs. The architecture is intended for state-heavy workloads where repeated scans, sync, replay, reconstruction, or full-state movement dominate the cost; it is not positioned as a general-purpose CPU replacement.

Hardware-Validated UI Proof

ATOMiK Desk v0.40-A prototype UI captured live from the framebuffer on Zynq hardware

HARDWARE_VALIDATED: ATOMiK Desk v0.40-A prototype UI captured from /dev/fb0 on live Zynq hardware, with on-screen metrics driven by real measured on-board data. This proves the current live demo surface, not commercial product maturity, performance, power, thermal, battery, water, or footprint outcomes.

Proof Stack

Proof	Label	Status
Zynq Desk v0.40-A	HARDWARE_VALIDATED	current public proof image, captured from /dev/fb0
Live Workloads demo on AX7020	LIVE_MEASURED	first customer-facing workload demo on hardware: 800 Mevents/s @ 8 banks, byte-identical
Parallel-bank throughput on AX7020	LIVE_MEASURED	8-bank accumulator scales 1/2/4/8x, byte-identical to software
Linux userspace to FPGA path	HARDWARE_VALIDATED	documented OS-to-bus validation path
AX7020 board run matrix	LIVE_MEASURED	raw artifact with interpretation caveats and workload-specific wins/losses
Formal proof work	SOFTWARE_VALIDATED	algebraic proof work in repo; avoid public counts until

Proof	Label	Status
Standalone SD boot artifacts	BUILD_ARTIFACT	audited across materials local build output exists; public power-on artifact is still a gate

Target Use Cases

Segment	Buyer pain	Evaluation metric
Edge / embedded systems	battery budget, enclosure heat, intermittent links, reliability	bytes moved, update latency, bandwidth, power proxy
AI at the edge	context/state movement, memory pressure, local response	transfers avoided, context retained, response latency
Remote / industrial / robotics / defense-adjacent	wattage, packet budget, field runtime, size/weight	runtime proxy, packet budget, update cost, reliability signal
Data center / infrastructure	power bill, cooling, water pressure, rack density	bytes moved, power/thermal proxy, measured workload energy path

The lead customer is the edge or embedded team that can bring one state-heavy workload, one current baseline, and one painful constraint.

Evaluation Offer

Give us one state-heavy workload, your current baseline, and the constraint that already hurts. We evaluate where state movement creates waste and whether ATOMiK can improve the path. You receive a workload map, baseline comparison, evidence map, fit/no-fit recommendation, and next-step plan. Success looks like measured improvement against one agreed metric while preserving correctness.

Business Path

Near term: paid proof reviews, technical evaluations, design partners, IP strengthening, and ASIC feasibility review.

Longer term: strategic licensing or integration partnership optionality only if workload proof and IP diligence justify it.

Pre-Seed Use Of Funds

- Convert provisional IP protection into stronger patent coverage.
- Run customer workload evaluations around state paths tied to battery, heat, power, bandwidth, latency, and footprint pressure.
- Bring in fractional CFO support for valuation and financing structure.

- Add ASIC mentorship before any tape-out decision.
- Package the Zynq demo into a lower-friction investor and customer proof system.

Financial Discipline

The current working ask is a \$2.0M target pre-seed, with a \$1.25M minimum viable close and a \$2.75M stretch plan. The round funds customer workload measurements, IP strengthening, CFO-reviewed financing structure, demo hardening, and ASIC feasibility. It does not fund tape-out.

Market benchmarks are context only: IEA/LBNL support the energy, cooling, and water-pressure urgency; Carta/PitchBook/NVCA support financing market context; SIA/WSTS supports the semiconductor-market backdrop. None of those sources prove ATOMiK savings or set ATOMiK's valuation.

Ask

ATOMiK is seeking a \$2.0M target pre-seed, design-partner introductions, ASIC/IP diligence support, and customer workloads where battery, heat, power, bandwidth, latency, reliability, or footprint are already painful. Final financing terms require CFO/counsel approval.
